

Architecture Blueprints

Architecture blueprints refer to a visual representation of the solution and how its capabilities support the business. The blueprint provides a conceptual view and helps the customer make key decisions and identify potential risks.

Four key benefits

The benefits of architecture blueprint:

1. Allows consumers to obtain a shared conceptual view of the solution
 2. Enables the organization to make informed decisions
 3. Identify potential risks with the solution
 4. Zero in on complexity by easily identifying the most complex parts of the solution
-

Components of an architecture blueprint

Business capability map

The business capability map is a diagram of the organization's business capabilities that are provided or enabled by the solution.

To create a business capability map, follow these steps:

1. Diagram each of the organization's core business units
 2. Group the organization's business capabilities with each business unit
 3. Define which business capabilities will be supported by the ServiceNow solution by working closely with the enterprise architect and program director
 4. Provide a visual representation of this by highlighting which capabilities are in scope for the solution
-

ServiceNow capability map

The ServiceNow capability map is a diagram of all ServiceNow capabilities that details which capabilities are in-scope for the solution and enable business outcomes for the customer.

To create a ServiceNow capability map:

1. Diagram each of the ServiceNow products by product area
2. Add context to the diagram by highlighting each of the capabilities

Service alignment map

The service alignment map is a diagram of the organization's business units and their alignment with ServiceNow capabilities that support them.

To create a service alignment map:

1. Diagram each of the business units that are affected by the solution
2. Continue to provide context to the diagram (i.e., align each of the ServiceNow capabilities that provide the functionality to each business unit)

Phased interactions map

The phased interactions diagram is like the ServiceNow capability map. However, instead of showing an overall picture of the products in use, it shows how products will be implemented in phases.

To create a phased interaction diagram:

1. Begin with the ServiceNow capability map diagram
2. Highlight each product according to the phase of implementation
3. Provide documentation that shows the linkage of the products included in each phase with the high-level outcomes that are supported through the implementation

High-level integration architecture

The integrations architecture diagram shows the high-level integrations between ServiceNow and external systems that bring additional value to the solution and support the organizations outcomes.

To create an integration architecture diagram:

1. Identify the integrations that are critical to the success of the solution and plot each of these within the diagram
 2. Identify the capabilities impacted by each integration
 3. Finalize the diagram by mapping each external application to the capability that it supports, or each capability that supports an external application/capability
-

QUICK REFERENCE GUIDE

Instance structure

Instance structure defines your ServiceNow instance setup and support model. It is the foundational component of the environment management domain within the technical governance.

To create an instance structure diagram:

1. Define your instance structure by determining the instance stack
2. Consider items such as the development process standards set by the organization and governance board. Also, consider the effort involved in keeping instances in sync and the number of development teams working with ServiceNow applications
3. Plot each instance in the diagram once you've identified each of the instances within the stack
4. Show the relationships of code migration and clones to provide visibility of how the instances interact and support the development process
