

Scoped Applications

Each ServiceNow application has an application scope that determines which of its resources are available to other parts of the system. Private application scope is commonly referred as scoped apps.

Steps to create an application

1. Understand business requirements
2. Build the application
3. Test the application
4. Share the application

Application publishing methods and their repositories

- ServiceNow store repository
- Application repository
- GIT repository
- Team development repository
- Update set

Cross-scope privileges

ServiceNow separates the assets and capabilities of one application from another, as well as the underlying platform itself, through application scope. Sometimes your customer's application may need to access an API provided by another application or the platform and needs to cross a scope boundary.

- When the application has been installed on an instance (also known as 'run-time'), the system switches from tracking to enforcing the cross-scope resources used.
 - Any time your application attempts to use a resource from outside its scope, the system validates that there is a `sys_scope_privilege` record that declares your application is known to use this resource in this way.
 - If there is no `sys_scope_privilege` record detailing that access, the system prevents it, and your users see a warning message.
-

QUICK REFERENCE GUIDE

An application development team needs to consider these things:

- The correct data model, which is the foundation of an application
- All relevant personas and their languages
- Documentation and who will support it
- Integrations - Exchanging data from ServiceNow to other external services
- Data imports/exports
- Reusability - Focus on reducing maintenance and avoiding the copy and paste mentality
- Clicks not code - Leverage a library of flows for reusable content and call actions from a script
- Need for many-to-many tables
- Need for extended table or extended table hierarchy
