

Integration Protocols and IntegrationHub

The APIs and integration tools available on the ServiceNow Platform enable anyone to easily create end-to-end digital workflows with a wide range of third-party applications and data sources both inside and outside the enterprise. Customers can easily integrate with business apps using out of the box integrations from the ServiceNow Store or they can create enterprise-grade integrations with scripts, protocols, and advanced features. ServiceNow's IntegrationHub is the most straightforward way to integrate and automate ServiceNow with anything (third-party API).

Integration options

Four options are available for customers to integrate with external applications and data sources.

- ServiceNow application included integration
- ServiceNow store integrations
- IntegrationHub spokes
- Build your own

Integration protocols

There are three methods to integrate ServiceNow with third-party applications and data sources.

- **Web services** allow bi-directional access to data-level integrations, as well as defining process-based web services that serve as a trigger for a process or a composite of actions
 - **Import sets** allow loading external data from various sources such as HTTPS, FTPS, and SCP using formats such as XML, CSV, and Microsoft Excel XLS
 - **Other:** API and command-line integrations can be implemented using a MID server
-

QUICK REFERENCE GUIDE

Technical components of integrations

The following technical components need to be considered for each integration:

Protocol	Message	Security
The API protocol determines the technical implementation	Using appropriate message formats reduces customization	Data-in-transit can be secured using various standards
REST	JSON	None
SOAP	XML	Basic
SFTP	File	OAuth 2.0
LDAP	GraphQL	Token
Other	Other	SAML 2.0

IntegrationHub benefits

IntegrationHub allows the organization to easily transform experiences and break out of restrictive silos.

IntegrationHub has many advantages:

- **Now Support integrated with Flow Designer** and thus integrations can be encapsulated within flows, capturing the integration in a wider context of a business/process logic and automation
- **Faster and simpler integration implementation** with the use of spokes, which reduces requirements for complex and custom code
- **Use native protocols to create custom spokes** such as REST, SSH, JDBC, and if required, the functionality to create custom spokes

Web services in ServiceNow

When planning web service integrations, a web service provider and a web service consumer need to be defined. ServiceNow can be configured to serve either role.
